## Description

Background of the Invention

This invention relates to certain pharmaceutically active substituted heterocyclic derivatives, pharmaceutical compositions containing them and methods of administering them to subjects in need of their corticotropin releasing factor antagonist activity.

The substituted heterocyclic derivatives claimed in this case exhibit activity as corticotropin releasing factor CRF antagonists.

CRF antagonists are referred to in U.S. Patents 4,605,642 and 5,063,245, which relate, respectively, to peptides and pyrazolinones, and were issued, respectively, on August 12, 1986 and November 5, 1991. They are also referred to in the following: PCT Patent Application PCT/IB95/00439, which designates the United States and was filed on June 6, 1995; PCT Patent Application PCT/IB95/00373, which designates the United States and was filed on May 18, 1995; U.S. Patent Application 08/448,539, which was filed in the PCT on Nov. 12, 1993 and entered the U.S. national phase on June 14, 1995; U.S. Patent Application 08/481,413, which was filed in the PCT on November 26, 1993 and entered the U.S. national phase on July 24, 1995; and U.S. Patent Application 08/254,820, which was filed on April 19, 1995. All the foregoing patents and patent applications are incorporated herein by reference in their entireties.

The importance of CRF antagonists is discussed in the literature, e.g., as discussed in U.S. Patent 5,063,245, which is incorporated herein by reference in its entirety. A recent outline of the different activities possessed by CRF antagonists is found in M. J. Owens *et al.*, *Pharm. Rev.*, Vol. 43, pages 425 to 473 (1991), also incorporated herein by reference. Based on the research described in these two and other references, CRF antagonists are effective in the treatment of a wide range of stress-related illnesses, such as depression, anxiety, headache, irritable bowel syndrome, inflammatory diseases, immune suppression, Alzheimers disease, gastrointestinal diseases, anorexia nervosa, hemorrhagic stress, drug and alcohol withdrawal symptoms, drug addiction, infertility, head trauma, stroke, and stress-induced infections in humans and animals.

This reaction can be conveniently carried out in the absence of a solvent at temperatures ranging from about 100°C to about 250°C.

Compounds of formula IV-O may be prepared by reacting the corresponding compounds of formula IX wherein A, T, R<sup>19</sup> and R<sup>4</sup> are defined as above with BNHNH<sub>2</sub> in an appropriate solvent as shown in Scheme 7. Suitable solvents include C<sub>1</sub>-C<sub>5</sub> alcohols, acetonitrile, toluene, chlorobenzene, xylene, toluene, dioxane, chloroform and methylene chloride, preferably in i-propanol or acetonitrile.

Compounds of the formula I-Q can be prepared as illustrated in Scheme 8. Compounds of formula XI wherein B is CR<sup>1</sup>R<sup>2</sup>R<sup>10</sup> or CN, X is O, S, NH, N(C<sub>1</sub>-C<sub>4</sub> alkyl), and R<sup>10</sup>, A, Z, R<sup>5</sup> are defined as above may be prepared by reacting compounds of formula X with hydroxylamine·HCl in a mixture of a solvent selected from C<sub>1</sub>-C<sub>5</sub> alcohols, CH<sub>3</sub>CN, acetone, dioxane and water, with or without sodium acetate, at a temperature from about room temperature to about 120°C, preferably at about the reflux temperature. Compounds of formula XI can then be reacted with an appropriate agent convert the hydroxy group of the oxime into a good leaving group such as -OAc, -OCOCF<sub>3</sub>, -OSO<sub>2</sub>CF<sub>3</sub>, -OSO<sub>2</sub>CH<sub>3</sub> or -OSO<sub>2</sub>C<sub>6</sub>H<sub>5</sub>CH<sub>3</sub> (p-tosylate). Examples of such appropriate agents are acetic anhydride, trifluoroacetic anhydride, triflic anhydride, methanesulfonyl chloride and p-toluenesulfonyl chloride. This reaction is generally conducted in an appropriate solvent such as methylene chloride, chloroform, acetonitrile, acetone, THF or pyridine, with or without a base such as N,N-dimethylpyridine or a tri(C<sub>1</sub>-C<sub>8</sub> alkyl) amine, at temperature from about 0°C to about 120°C, preferably from about room temperature to about 80°C. Most preferably, an excess of acetic anhydride is used at a temperature between 80°C and the reflux temperature. The resulting compounds can then be heated in an appropriate solvent such as DMF, DMSO, sulfolane, dioxane, THF or NMP in the presence of base such as pyridine, a tri(C<sub>1</sub>-C<sub>4</sub> alkyl) amine or sodium hydride, at temperature from about 0°C to about 180°C, preferably from about room temperature to about 150°C, to give the final cyclized compounds of formula I-Q.

Compounds of formula I-Q wherein B is -CN can be converted into the corresponding compounds wherein B is NR<sup>1</sup>R<sup>2</sup> or NHCR<sup>1</sup>R<sup>2</sup>R<sup>10</sup> using a Curtius rearrangement reaction, as described below. Compounds of formula I-Q wherein B is CN are subjected to acid hydrolysis with, e.g., aqueous phosphoric acid, at a temperature between about 80°C and about 150°C, to yield the corresponding compounds wherein B is COOH. Compounds of the formula I-Q wherein B is COOH can be converted into the corresponding compounds wherein B is -NH<sub>2</sub> by reacting them with diphenylphosphorylazide in t-butyl alcohol in the presence of a tri(C<sub>1</sub>-C<sub>4</sub> alkyl) amine, followed by acid hydrolysis using, e.g., trifluoroacetic acid, according to procedures well known in the art. The amino derivatives so formed can be converted, also using standard methods well known in the art, into the corresponding compounds wherein B is NR<sup>1</sup>R<sup>2</sup>R<sup>10</sup> via an alkylation or reduction amination reaction. Such a procedure is described above for forming compounds of the formula IB.

Reaction of compounds of formula I-Q wherein B is CN with a Grignard reagent (e.g., R<sup>2</sup>MgX' wherein X' is halo) at a temperature from about 0°C to about room temperature in THF, ether or dioxane, followed by quenching with an acid, using the conditions well known in the art, will afford the corresponding ketones of formula I-Q wherein B is COR<sup>2</sup>. Reduction of such ketones with sodium borohydride in a C<sub>1</sub>-C<sub>5</sub> alkyl alcohol will afford the corresponding compounds of formula I-Q wherein B is CHR<sup>2</sup>OH. Alkylation of compounds of formula I-Q wherein B is CHR<sup>2</sup>OH with R<sup>1</sup>-L (wherein L is a leaving group such as halo, mesylate or tosylate) in the presence of a base such as sodium hydride or potassium hydride will yield the corresponding compounds wherein B is CHR<sup>1</sup>R<sup>2</sup>. This reaction is typically carried in an appropriate solvent, e.g., THF, dioxane, ether, toluene or DMSO, at temperature between about 0°C and about 100°C, preferably between about 0°C and about room temperature.

The starting materials and intermediates of formulas IV, V, VI, VII, VIII, IX and X are commercially available, known in the art, or able to be synthesized using the procedures disclosed in PCT Patent Application PCT/IB95/00439, PCT Patent Application PCT/IB95/00373, U.S. Patent Application 08/481,413, U.S. Patent Application 08/448,539, and U.S. Patent Application 08/254,820, all of which are referred to and incorporated herein by reference in their entireties above.

In each of the above reactions, pressure is not critical. Pressures in the range of about 0.5-20 atm (0.5-20 bars) are suitable, and ambient pressure (generally, about one atmosphere) is preferred as a matter of convenience. Also, for those reactions where the preferred temperature varies with the particular compounds reacted, no preferred temperature is stated. For such reactions, preferred temperatures for particular reactants may be determined by monitoring the reaction using thin layer chromatography or gas chromatography/mass spectroscopy.

The preparation of other compounds of the formula I not specifically described in the foregoing experimental section can be accomplished using combinations or variations of the reactions described above that will be apparent to those

skilled in the art.

Compounds of the formulas I, II and III that are basic in nature are capable of forming a wide variety of different salts with various inorganic and organic acids. Although such salts must be pharmaceutically acceptable for administration to animals, it is often desirable in practice to initially isolate a compound of the formulas I, II or III from the reaction mixture as a pharmaceutically unacceptable salt and then simply convert the latter back to the free base compound by treatment with an alkaline reagent, and subsequently convert the latter free base to a pharmaceutically acceptable acid addition salt. The acid addition salts of compounds of the formulas I, II and III can be prepared in a conventional manner by treating a solution or suspension of the corresponding free base with one chemical equivalent of a pharmaceutically acceptable acid. Conventional concentration or crystallization techniques can be employed to isolate the salts. Illustrative of suitable acids are acetic, lactic, succinic, maleic, tartaric, citric, gluconic, ascorbic, benzoic, cinnamic, fumaric, sulfuric, phosphoric, hydrochloric, hydrobromic, hydroiodic, sulfamic, sulfonic acids such as methanesulfonic, benzene sulfonic, p-toluenesulfonic, and related acids.

Compounds of the formulas I, II and III that are also acidic in nature, are capable of forming base salts with various pharmacologically acceptable cations. Examples of such salts include the alkali metal or alkaline-earth metal salts and particularly, the sodium and potassium salts. These salts are all prepared by conventional techniques. The chemical bases which are used as reagents to prepare the pharmaceutically acceptable base salts of this invention are those which form non-toxic base salts with the acidic compounds of formula I. Such non-toxic base salts include those derived from such pharmacologically acceptable cations as sodium, potassium calcium and magnesium, etc. These salts can easily be prepared by treating the corresponding acidic compounds with an aqueous solution containing the desired pharmacologically acceptable cations, and then evaporating the resulting solution to dryness, preferably under reduced pressure. Alternatively, they may also be prepared by mixing lower alkanolic solutions of the acidic compounds and the desired alkali metal alkoxide together, and then evaporating the resulting solution to dryness in the same manner as before. In either case, stoichiometric quantities of reagents are preferably employed in order to ensure completeness of reaction and maximum yields of the desired final product.

The active compounds of this invention may be administered alone or in combination with pharmaceutically acceptable carriers, in either single or multiple doses. Suitable pharmaceutical carriers include inert solid diluents or fillers, sterile aqueous solutions and various organic solvents. The pharmaceutical compositions formed by combining the novel compounds of formulas I, II and III and their pharmaceutically acceptable carriers can then be readily administered in a variety of dosage forms such as tablets, powders, lozenges, syrups, injectable solutions and the like. These pharmaceutical compositions can, if desired, contain additional ingredients such as flavorings, binders, excipients and the like. Thus, for purposes of oral administration, tablets containing various excipients such as sodium citrate, calcium carbonate and calcium phosphate may be employed along with various disintegrants such as starch, methylcellulose, alginic acid and certain complex silicates, together with binding agents such as polyvinylpyrrolidone, sucrose, gelatin and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often useful for tableting purposes. Solid compositions of a similar type may also be employed as fillers in soft and hard filled gelatin capsules. Preferred materials for this include lactose or milk sugar and high molecular weight polyethylene glycols. When aqueous suspensions or elixirs are desired for oral administration, the essential active ingredient therein may be combined with various sweetening or flavoring agents, coloring matter or dyes and, if desired, emulsifying or suspending agents, together with diluents such as water, ethanol, propylene glycol, glycerin and combinations thereof.

For parenteral administration, solutions containing an active compound of this invention or a pharmaceutically acceptable salt thereof in sesame or peanut oil, aqueous propylene glycol, or in sterile aqueous solution may be employed. Such aqueous solutions should be suitably buffered if necessary and the liquid diluent first rendered isotonic with sufficient saline or glucose. These particular aqueous solutions are especially suitable for intravenous, intramuscular, subcutaneous and intraperitoneal administration. The sterile aqueous media employed are all readily available by standard techniques known to those skilled in the art.

The effective dosages for compounds of the formulas I, II or III and their salts will depend on the intended route of administration and factors such as the age and weight of the patient, as generally known to a physician. The dosages will also depend on the particular illness to be treated. For instance, the daily dosage for stress-induced illnesses, inflammatory disorders, Alzheimer's disease, gastro-intestinal diseases, anorexia nervosa, hemorrhagic stress and drug and alcohol withdrawal symptoms will generally range from about 0.1 to about 50 mg/kg body weight of the patient to be treated.

Methods that may be used to determine the CRF antagonist activity of the active compounds of this invention and their pharmaceutically acceptable salts are described in Endocrinology, 116, 1653-1659 (1985) and Peptides, 10, 179-188 (1985). The binding activities for compounds of formulas I, II and III, expressed as  $IC_{50}$  values, generally range from about 0.5 nanomolar to about 10 micromolar.

The present invention is illustrated by the following examples. It will be understood, however, that the invention is not limited to the specific details of these examples. Melting points are uncorrected. Proton nuclear magnetic resonance

spectra ( $^1\text{H}$  NMR) and  $\text{C}^{13}$  nuclear magnetic resonance spectra ( $\text{C}^{13}$  NMR) were measured for solutions in deuteriochloroform ( $\text{CDCl}_3$ ) and peak positions are expressed in parts per million (ppm) downfield from tetramethylsilane (TMS). The peak shapes are denoted as follows: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; b, broad.

The following abbreviations are used in the Examples: Ph=phenyl; iPr=isopropyl; HRMS=high resolution mass spectrum.
